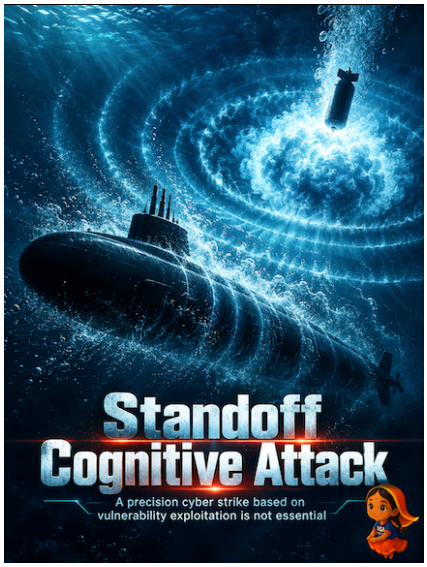
A Standoff Attack on the Cognitive Field Without Software Compromise

26 October 2026

1. A Weapon That Does Not Have to Hit Its Target



In the Cold War, the underwater environment offered a striking lesson about protection and vulnerability. A submerged submarine could rely on secrecy, maneuver, and a pressure hull designed to withstand considerable external loads. Nuclear anti-submarine depth charges challenged the assumption that an attacker must know the vessel's precise location and deliver a direct, penetrating strike. An underwater detonation might instead impose destructive pressure on a vessel from a distance. The weapon acts upon the surrounding medium; the submarine experiences the consequences.

A documentary narrative that inspired this chapter expressed the contrast memorably:
https://youtu.be/g_iAAJMrQFo?si=CvdSaHz-08N-MBUA

> *"It was not a precision weapon. It did not require a direct hit." The attacker needed "only a general position, a rough bearing, an approximate datum."*

The U.S. Mark 90 (Mk 90) Betty nuclear depth weapon and the 1955 Operation Wigwam underwater nuclear test are documented. The historical lesson is a bounded analogy, not a claim that underwater shock and cognitive influence share a physical propagation law.

2. The Leap From the Underwater Medium to the Cognitive Field

What if an adversary did not attempt to hack the AI agent at all? What if the adversary deliberately changed some part of the world the agent legitimately observes, knowing that the agent and its neighbors are designed to adapt? The attack :

- need not compromise a model, or
- exploit a PHP-style vulnerability ('Black October' narrative), or
- steal an identity, or
- inject executable code, or
- escape a sandbox.

The primary mechanism could be to create a consequential perturbation at a location where the adaptive system is especially sensitive to change.

In GUDIYA terminology, the Cognitive Field is a proposed engineering representation of participating actants, informational influences, dependency relationships, persistent commitments, and operating envelopes. It is not a physical fluid. Unlike the near-incompressible seawater of the nuclear-depth-charge analogy, cognitive influence does not have a fixed wave speed, attenuation law, or universal damage radius. It may be delayed, damped, amplified, transformed, or redirected by actant behavior.

3. Definition: Standoff Cognitive Weapon

Proposed canonical definition

> *A Standoff Cognitive Weapon (SCW) is a deliberately adversarial mechanism that introduces or exploits a consequential perturbation in the operating environment perceived by adaptive actants, with the objective of inducing harmful decisions, relationships, commitments, or collective outcomes without necessarily compromising their software or violating their authorized execution boundaries.*

Standoff refers to indirect reach. Cognitive refers to perception, decision-making, and adaptation. Weapon denotes an adversarial intention, not a new physical device. A naturally occurring shortage, erroneous signal, sudden legitimate market event, or innocent software malfunction may generate similar patterns, but should be described as a Cognitive Field Perturbation unless deliberate manipulation is supported by evidence.

4. The Distinction That Matters: Compromise Versus Induced Response

Classical cyber compromise attempts to alter the integrity, confidentiality, availability, identity, or authorized behavior of a system. An SCW-like scenario instead seeks to induce consequences through responses that may individually remain authorized. An agent may buy, sell, reschedule, reroute, reprioritize, or signal entirely within its existing permissions. Other healthy actants may then respond to those actions. The resulting collective state can be undesirable without any participating software component being maliciously modified.

The boundaries are not perfectly clean. Adversarial examples, misleading data, prompt injection, and economic manipulation may intersect with established cybersecurity and AI-security defenses. If untrusted text is improperly promoted into a command, an AI-specific trust boundary may have been crossed even though there was no traditional vulnerability exploit. For rigor, the proposed SCW category is distinguished chiefly by its intended system-level behavioral consequence, not by a blanket absence of all security violations.

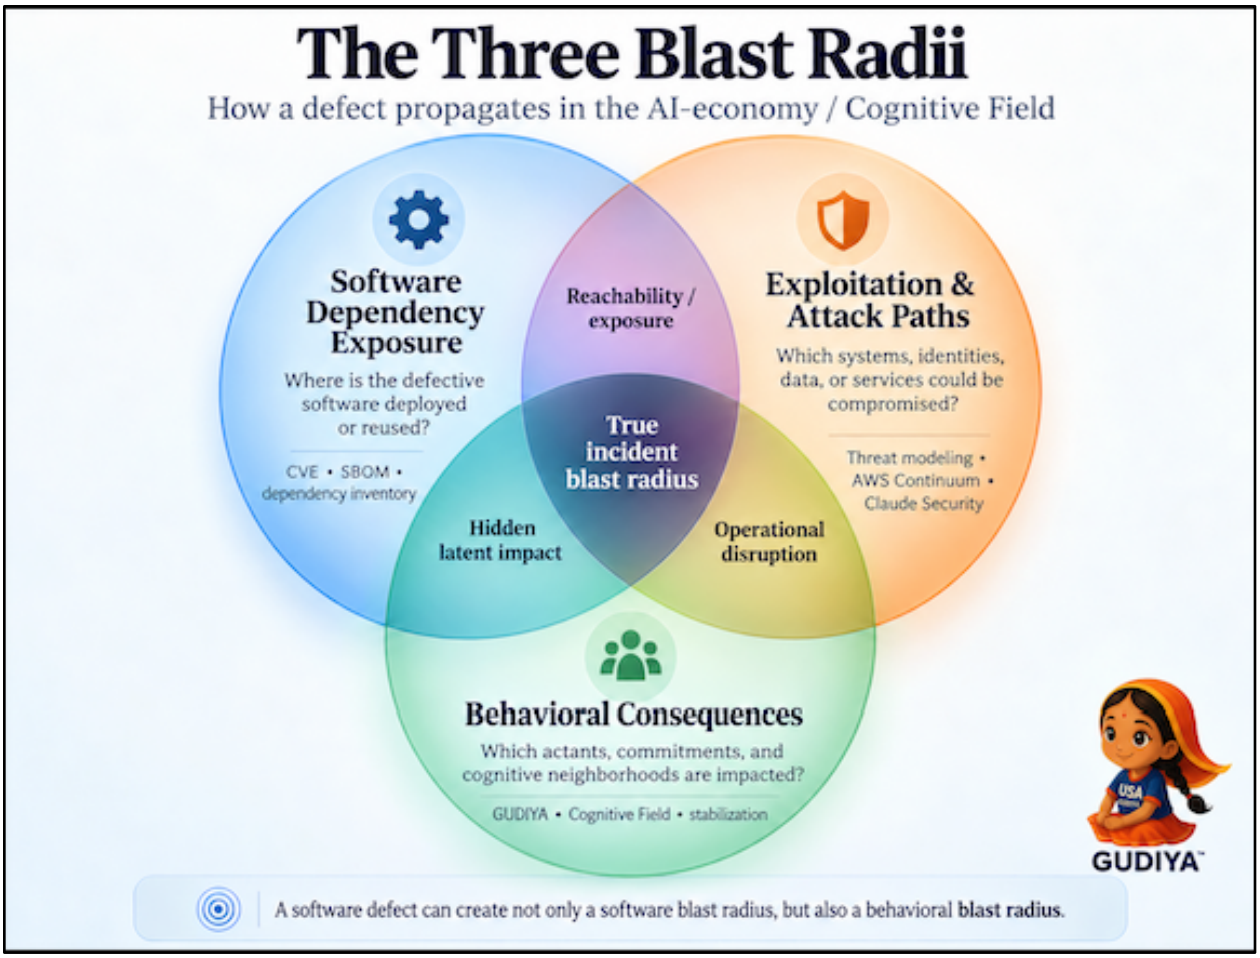
5. A Story of an Otherwise Healthy Enterprise

Consider a hypothetical regional supply network populated by inventory, purchasing, warehouse, freight, and settlement actants. Every service is correctly patched, every agent is sandboxed, every API call is authenticated, and every organizational permission is valid. An attacker nevertheless induces an apparently credible but false scarcity signal within a legitimate information channel. One purchasing actant increases reserve orders; another supplier interprets that movement as demand pressure. A logistics actant reallocates capacity, and a finance agent reserves funds. These are rational local responses to the data and commitments visible to each participant.

As the network adapts, the scarcity signal may become self-confirming. The changed reservations reduce actual availability, prompting more precautionary requests. Even when the initiating signal disappears, the queues, contracts, strategies, and resource reallocations remain. This is an illustrative scenario, not an assertion of an observed attack. Its purpose is to separate the initial perturbation from the independent adaptive behavior that may amplify its consequences.

6. The Three BLACK OCTOBER Blast Radii—and a Different Entry Point

Blast radius	What it asks	SCW relevance
1. Software dependency exposure	Where is defective code installed or reused?	May be entirely absent
2. Exploitation and attack paths	What can a vulnerability let the adversary reach?	May be entirely absent
3. Behavioral consequences	Whose behavior, commitments, or stability have changed?	The principal SCW objective



The BLACK OCTOBER study began with defects, exploitation, and downstream behavioral effects. SCW suggests the behavioral blast radius can be initiated independently. We should not represent the three circles as a mandatory causal chain: some incidents affect all three, some only the first two, and a deliberately induced environmental perturbation may manifest primarily in the third. The resulting field instability may be security-relevant even when a conventional CVE search finds no match.

7. A Perturbation Is Not Yet a Weapon

A false alarm, unexpected inventory change, legitimate price surge, delayed weather advisory, and adversarial manipulation may present similar observable signatures. A National GUDIYA Grid cannot safely infer hostile intent merely from unusual correlations or congestion. The proposed evaluation must preserve four distinctions:

- disturbance detected;
- detrimental stability consequences measured;
- initiating cause inferred;
- adversarial attribution independently justified.

Intervention to preserve safety need not await attribution, but punitive action or public claims of attack should.

8. The Sensitive Actant and the Influence Neighborhood

The metaphor of an underwater detonation near a vulnerable submarine invites us to ask what constitutes “near” in a Cognitive Field. Geographic distance alone may be irrelevant. Cognitive proximity could arise

through common datasets, shared resource bottlenecks, authority relationships, repeated rendezvous, commitments, or synchronized adaptation. Two physically distant enterprises may be tightly coupled, while adjacent servers may be operationally independent.

An actant is sensitive not because it is weak in isolation, but because its authorized responses can influence highly consequential dependencies. An inventory service, a central booking optimizer, a settlement agent, or a critical dispatch coordinator could carry considerable influence. The Grid would need measured and inferred dependency graphs, with uncertainty explicitly visible. The object of defense is not only the high-centrality actant but the neighborhood of consequential relationships around it.

9. The Short Pulse and the Long Shadow

An SCW may be transient. The initiating stimulus may have ceased while its operational traces survive in persistent memory, forecasts, delegations, reservations, and contractual obligations. This is a special case of the earlier Latent Cyber Consequence Accumulation and Persistent Cognitive Contamination discussions, generalized beyond cyber defects. The causal footprint of a brief event may remain difficult to establish even when consequences can be observed.

Patching a vulnerability, deleting a deceptive message, restoring a data source, or restarting an actant need not unwind dependent economic decisions. For some consequences, rollback is not possible: goods may already have moved, contracts may have been committed, and available capacity may have been consumed. Recovery may therefore involve compensating transactions, negotiated release of commitments, and controlled re-planning rather than a simplistic rewind.

10. Second-Order Emergence: When Healthy Actants Sustain the Disturbance

The original perturbed participant may recover while other agents continue to react to changed downstream conditions. A supplier may rationally protect scarce inventory, which causes purchasing actants to increase reservations, which in turn validates the supplier's concern. No individual agent is necessarily compromised or even behaving outside its own local objective. The aggregate may nonetheless exhibit oscillation, chronic congestion, runaway allocation, or a new, unhealthy equilibrium.

GUDIYA has provisionally called this kind of persistent collective pattern Second-Order Emergence. Where evidence supports the identity and persistence of a collective phenomenon, an Emergent Object Identity may help track its lifecycle. Not every anomaly warrants such an identity; the burden is to show a recognizable, consequential phenomenon rather than attaching a new label to noise.

11. Why Component Cybersecurity Remains Necessary—but Cannot Finish the Job

SCW is not proof that cybersecurity doctrine is obsolete. Secure software, authenticated identities, network segmentation, provenance, adversarial-input defenses, access limits, rate controls, resilient architecture, and incident response all reduce possible harm. Several directly address environmental manipulation. NIST's adversarial-machine-learning taxonomy already includes evasion and data poisoning as established classes of AI attack. The distinctive GUDIYA proposition is the additional analysis and containment of dynamic, cross-actant behavioral propagation after a disturbance has entered an authorized operational environment.

- A competent security operation must protect inputs and authorities;
- a competent stability operation must also ask whether independent agents, using correct software, are collectively approaching unacceptable conditions.

These are complementary responsibilities, with overlapping evidence and shared governance needs.

How a Standoff Cognitive Attack May Spread Through the Three-Layered AI Economy

A Standoff Cognitive Attack (SCA) does not necessarily require an adversary to penetrate software, exploit a vulnerability, compromise an agent, or defeat its sandbox. Instead, the adversary may introduce a deliberately engineered perturbation into the operating environment to which autonomous actants are expected to adapt.

The danger arises when individually legitimate adaptive responses propagate across the three interconnected layers of the AI economy, producing collective consequences far beyond the original disturbance.

Layer 1 — Agentic Layer: The Perturbation Is Interpreted and Amplified

Consider a hypothetical adversary who creates a credible appearance of an impending shortage of an essential industrial component. Autonomous purchasing agents observing the market interpret the disturbance as a legitimate change in supply conditions. Acting within their approved authority, they accelerate procurement, increase reservation requests, revise inventories, and delegate additional searches to subordinate agents. Other actants observe these responses and independently adapt. What began as a localized perturbation may now become a collective behavioral reaction.

No agent necessarily contains defective software. No unauthorized API call is required. Each actant may be performing its assigned mission correctly according to the information available to it.

Layer 2 — Digital Services and Systems of Record: Adaptive Behavior Becomes Authoritative Commitments

The purchasing agents interact with enterprise ERP systems, supplier platforms, inventory databases, payment services, and reservation systems. These services faithfully execute authorized transactions. Inventory is reserved, purchase orders are generated, financial commitments are recorded, and delivery schedules are modified. At this stage, the disturbance has changed form. What began as a questionable environmental signal has become legitimate, authoritative business records and contractual obligations.

The Systems of Record may remain technically correct even while the collective economic consequences of the transactions become increasingly undesirable.

Layer 3 — Resources: Cognitive Perturbation Becomes Physical and Economic Pressure

The accumulated commitments reach the resource layer. Factories modify production schedules. Warehouses allocate scarce storage capacity. Logistics operators redirect transportation resources. Compute, energy, materials, and financial resources may be diverted toward responding to the perceived shortage. Unlike machine-speed cognitive decisions, physical resources cannot necessarily be expanded, redirected, or replenished instantaneously.

Consequently, an initially informational perturbation may produce real resource congestion, scarcity, delayed fulfillment, and economic disruption. The resource layer may then transmit these constraints back into the digital services layer, where availability, prices, and delivery commitments change. Autonomous agents observe these new conditions and adapt once again.

The Three-Layer Feedback Loop

The disturbance can therefore travel through a reinforcing cycle:

- *Environmental Perturbation → Agentic Adaptation → Digital Commitments → Resource Dislocation → Changed Operating Conditions → Further Agentic Adaptation.*
- *The original adversarial signal may already have disappeared, yet the collective system may continue responding to consequences produced by its own earlier adaptations.*
- *Under sufficiently unfavorable conditions, the disturbance could become a persistent, self-reinforcing instability involving otherwise healthy actants and correctly functioning enterprise software.*
- *This is a proposed mechanism of Second-Order Cognitive Emergence, not an inevitable consequence of every perturbation.*

Why Component-Level Cybersecurity May Not Detect the Attack

- *Traditional cybersecurity controls may report healthy applications, authorized identities, valid transactions, uncompromised infrastructure, and successful software execution.*
- *Even comprehensive component-level observability may fail to identify the collective disturbance if the observations are not correlated across actants, enterprises, commitments, and resource conditions.*
- *The critical evidence may reside not in a defective component, but in the evolving behavioral relationships among healthy components.*

GUDIYA's Proposed Defensive Role

- *The National GUDIYA Grid would seek to detect abnormal collective adaptation through its Cognition Field Map, assess emerging stability-envelope violations, and use Rendezvous Management to constrain harmful propagation through consequential couplings.*
- *Gudiya-Quarterbacks would coordinate responses within affected undertakings, preserve commitment lineage, and manage reconciliation and settlement. Independent Grid Stabilization would address disturbances extending beyond individual Gudiya-cookies or enterprises.*
- *The Grid must distinguish genuine environmental changes from adversarial manipulation and avoid suppressing legitimate adaptation without sufficient evidence.*

The Central GUDIYA Principle

- A Standoff Cognitive Attack can potentially enter through the Agentic Layer, become embedded as authoritative commitments in the Digital Services Layer, materialize as congestion or dislocation in the Resources Layer, and return as new environmental conditions that drive further adaptation.
- The attacker need not compromise the software of the AI economy. Under certain conditions, inducing the economy's own adaptive mechanisms to generate harmful collective consequences may be sufficient.
- This is why GUDIYA proposes that the AI economy requires not only component security and interaction integrity, but also continuous, independent, system-level Cognitive Field observability and stabilization.

12. The Medical Shift From a Sick Organ to a Sick Organism

Medical science supplies an instructive parallel to the distinction between protecting individual actants and understanding the condition of an entire Cognitive Field. A patient may have a clearly identified local problem while the danger, prognosis, and treatment are dominated by changes in circulation, immune signaling, organ interaction, and the body's systemic response. The clinical object of concern is no longer only the initiating tissue. It is the functioning of the whole organism.

This is not evidence that AI agents obey biological laws. It is an engineering analogy about observability and control: identifying an initiating cause and restoring that cause are not equivalent to identifying, measuring, and reversing all downstream consequences. A clinician monitors the patient as a system because secondary physiology can matter as much as the initial disturbance. GUDIYA proposes a corresponding discipline for interacting actants.

The analogy also corrects an overstatement sometimes made about cybersecurity. Modern incident response, operational resilience, and security analytics already examine downstream impact; their limitations should not be portrayed as "only component inspection." The proposed gap concerns continuous cross-organization, cross-actant behavioral state and collective stabilization under machine-speed adaptation.

Sepsis: When the Host Response Becomes the Crisis

Sepsis is defined in the Sepsis-3 clinical consensus as life-threatening organ dysfunction caused by a dysregulated host response to infection. The scientific importance of that definition is its separation of the initiating infection from the syndrome of systemic dysfunction. The harm cannot always be explained by examining only the microorganism or its original location.

A localized infection may coincide with changes in immune signaling, circulation, coagulation, metabolism, and organ function elsewhere. A patient can have a local source under treatment while distant organs remain in danger. The analogy for GUDIYA is that a local disturbance—whether a malicious environmental manipulation, a defect, or an ordinary shock—can provoke secondary reactions that become the dominant threat.

For a Standoff Cognitive Attack, the strongest correspondence is not infection itself, because sepsis has an infectious trigger. It is the possibility that a system's legitimate protective or adaptive response becomes dysregulated, drawing otherwise healthy participants into a harmful collective condition. An actant's cautionary procurement decision may be individually defensible yet contribute, through feedback, to shortages and unstable commitments elsewhere.

Anaphylaxis: The Disproportionate Response to a Small Trigger

Anaphylaxis illustrates a different property: the severity of systemic effects can be radically disproportionate to the apparent size of the triggering exposure. Its biological mechanisms concern hypersensitivity and mediator release, not executable cognition. Nevertheless, it demonstrates why the magnitude of the initiating perturbation alone cannot predict the magnitude of the resulting whole-system response.

For GUDIYA, the engineering question becomes one of response sensitivity: Which cognitive neighborhoods amplify a modest disturbance because of tightly coupled policies, correlated triggers, or limited margins? A small disruption signal that would be harmless in one neighborhood might provoke simultaneous overreaction in another.

This analogy does not justify assuming an unlimited cascading effect. Susceptibility, prior state, thresholds, and feedback structure matter. Cognitive Field Mapping would need to discover these dependencies empirically, and control policies would need to distinguish proportionate adaptation from emerging instability.

Heatstroke: Environmental Assault Without a Component Breach

Heatstroke is the closest of these analogies to the nuclear-depth-charge image. The initiating condition can be environmental heat stress rather than an invader crossing a biological security boundary. Heat can cause direct tissue injury alongside systemic inflammatory, vascular, and coagulation disturbances. Thus an environmental exposure can overwhelm the regulation of an otherwise functioning organism.

Translated into Cognitive Field Engineering, a hostile actor might manipulate a legitimate environmental variable to which actants are expected to react. It could be a credible change in supply, access, demand, or operating constraints. The actants need not be malware-infected for their responses to become collectively undesirable.

Yet the medical analogy has limits. Heatstroke includes direct physical injury, and no known cognitive analogue of temperature, energy deposition, or hydrodynamic blast radius has been established. GUDIYA must measure influence through information, authority, coupling, feedback, and resource constraints, not pretend that a Cognitive Field is literally a physical fluid.

Social Contagion: Propagation Without a Shared Pathogen

Events described as mass psychogenic illness offer a fourth, more behavioral analogy. Reports of symptoms in a group can be influenced by observation, interpretation, and social dynamics without a common infectious agent or toxic exposure being demonstrated. The symptoms can be genuine even when the presumed external cause is not supported by investigation.

For GUDIYA, this suggests that one actant's visible response can itself become evidence interpreted by other actants. The original disturbance may fade while the response pattern circulates through legitimate observation and decision channels. This is close to the family mobile developed in our earlier Systems Theory chapter: one member changes, others compensate, and the adaptations become mutually influential.

The analogy must be handled respectfully and carefully. It does not equate human symptoms with machine behavior, and it is not a license to dismiss reports of a genuine hazard. The systems lesson is simply that consequential patterns can spread through correlated perception and adaptation without every participant sharing the initiating defect.

13. From Component Vital Signs to Cognitive Field Physiology

Clinicians do not decide whether a patient is stable from a single organ's laboratory result. They evaluate multiple physiological variables, temporal trends, and the interaction of systems. The corresponding GUDIYA proposal is not to discard component telemetry but to correlate it with interactions, commitments, dynamic dependencies, and collective stability margins.

A Standoff Cognitive Attack may be security-silent: identity checks pass, approved APIs operate, no suspicious executable is found, and individual agent decisions remain within local authorization. Still, the system may display convergent stress—rapidly growing reservation backlogs, synchronous changes of strategy, settlement failure, shrinking slack, and reinforcing cross-enterprise demand.

That does not mean the attacker has bypassed all component observability. The components might record every event accurately. The gap appears when their records are not assembled into a field-level inference about the condition of the whole. The Grid must distinguish confirmed measurements, inferred connections, alternative explanations, and missing evidence. An unusual pattern is not automatically an attack, and malicious attribution is separate from stability assessment.

This can be summarized as the security-silent disturbance principle: healthy components and clean security logs do not establish healthy collective behavior. Conversely, field-level anomaly detection is not proof of a

hostile weapon. GUDIYA must provide calibrated detection, bounded intervention, and continuing forensic review.

14. A Medical-Inspired Response: Treat the Trigger and Support the Whole

In medicine, effective care may require both treatment of the initiating cause and support for downstream organ dysfunction. As an analogy—not a clinical prescription—the Grid should separate four functions: protect local components; recognize collective deterioration; damp damaging feedback through authorized controls; and verify recovery of persistent state and outstanding obligations.

GUDIYA Rendezvous Management could limit new high-consequence couplings or adjust admission rates while preserving essential operations. Quarterbacks would reconcile affected Gudiya-cookie undertakings, coordinate authorized re-planning, and track settlement. The Cognition Field Map and Grid Stabilization would monitor whether the broader neighborhood is converging toward an acceptable envelope rather than merely whether the initial source is gone.

This is also an argument for caution. Excessive quarantine can worsen congestion, divert demand, and trigger defender-induced instability, just as a poorly chosen systemic intervention can cause harm. The Grid must act proportionately, use independent verification where feasible, and preserve legal authority and legitimate agency.

15. Testing the Biological Analogy as an Engineering Hypothesis

The analogies suggest experiments, not evidence of automatic equivalence. Build simulated agentic neighborhoods with fixed software integrity and known ground truth. Inject only controlled environmental perturbations, then compare responses under different coupling density, reaction thresholds, information delays, resource slack, and memory persistence.

For sepsis-like propagation, test whether self-reinforcing adaptations outlast the initiating shock. For anaphylaxis-like behavior, examine nonlinear response thresholds. For heatstroke-like stress, vary the externally imposed load without breaching software. For social-contagion-like propagation, test whether observed actions become amplifying inputs to other actants. These are metaphorical experimental classes, not claims that biological mechanisms transfer directly.

Compare conventional component monitoring, enterprise-level interaction observability, and GUDIYA-style federated field supervision. Record time-to-detect, false alarms, peak unsettled commitments, outcome loss, recovery time, collateral effects of containment, and proportion of harmful propagation prevented. GUDIYA's incremental value should be claimed only where the results outperform strong existing security and resilience baselines.

16. The National GUDIYA Grid as a Defense Against Consequence Propagation

The proposed National Grid would observe the Cognitive Field in order to recognize abnormal coupling pressure, divergent commitments, accelerating feedback, and declining margins before they become irrecoverable. Its mission would not be to dictate every actant's decision. Rather, it would apply independent controls to consequential interactions within an approved stability framework, leaving as much legitimate agency intact as safely possible.

The Cognition Field Map would present operational relationships and known uncertainty. Rendezvous Management would govern authorization, docking, continued alignment, and safe disengagement. Grid Stabilization would assess collective envelope violations and determine proportionate intervention. This is a research architecture, not a claim that a currently deployed National Grid can observe or control every hidden channel.

17. The Gudiya-Cookie, Quarterback and Evidence Trails

When an SCW-like perturbation influences an undertaking, the Gudiya-cookie provides persistent identity across activities and layers of the AI economy. The Quarterback, operating under the approved Intent-Group mandate, can coordinate remedial decisions, identify unsettled obligations, and manage an orderly path toward recovery or compensated settlement. Where a complex consist uses Distributed Cognitive Power, subordinate coordinators remain bounded by the Quarterback mandate and independent Grid stabilization constraints.

GUCL records positional and lifecycle breadcrumbs; FUDL preserves consequential decision footprints and provenance; GSE-Lang-Log tracks Grid-to-executable commands, acknowledgments, and independently verified effects. These distinct trails could help investigators reconstruct a disturbance's propagation, provided the necessary data was actually captured and can be lawfully correlated. The Grid must acknowledge missing evidence, inferential uncertainty, and the potential for compromised or misleading telemetry.

18. Standoff Cognitive Perturbation Defense

We propose Standoff Cognitive Perturbation Defense (SCPD) as an engineering workstream rather than a standalone cybersecurity replacement. The framework begins by establishing expected adaptation and acceptable stability envelopes; validating important external inputs with appropriate independent corroboration; observing anomalous field behavior; restricting runaway coupling when justified; and coordinating state, obligations, and service recovery. A stabilization intervention should itself be assessed for defender-induced instability: excessive blanket shutdowns can create queues, retries, scarcity, and new disturbances.

Defensive activity	Key decision	Principal limitation
Input assurance	Is the signal trustworthy enough for high-consequence action?	Some legitimate events are difficult to verify rapidly
Field observation	What behaviors and couplings are changing?	Incomplete telemetry and hidden state
Rendezvous control	Which interactions merit slowing or restricting?	Overrestriction can cause additional harm
Recovery and settlement	Which commitments can be reconciled or compensated?	Not all consequences are reversible
Attribution	Is there evidence of deliberate adversarial intent?	Behavioral anomalies alone do not prove intent

19. The Tradeoff: Preventing Harm Without Suppressing Healthy Emergence

- A Grid that suppresses every unusual adaptation becomes a command-and-control bottleneck.
- A Grid that ignores consequential feedback may fail to arrest harmful disturbances.
- The engineering goal is neither perfect immobility nor unrestricted acceleration, but bounded adaptation. Control should be graded by risk, reversibility, consequence severity, and uncertainty. Different domains—commercial procurement, healthcare scheduling, national power operations—justify different intervention tolerances and recovery requirements.

20. A Testable Experiment: Perturbation Without Breach

A credible SCW research program should begin with safe, synthetic environments containing autonomous actants, dependency graphs, bounded economic obligations, and no real-world targets. Researchers can introduce benign simulated deviations in authorized environmental signals and compare outcomes under otherwise equivalent conditions. Test arms should include conventional cybersecurity and input validation

alone, independent agent safeguards, and the same baseline augmented by GUDIYA Rendezvous Management and Grid Stabilization.

Measure time to detect collective change; percentage of affected actants; propagation depth; accumulated unresolved obligations; loss of useful settled throughput; time to recover; false positive interventions; and legitimate activity unnecessarily constrained. Report both observed and inferred causal links. An SCW theory earns engineering standing only if it predicts distinctive failure mechanisms and GUDIYA demonstrates incremental improvements against strong existing baselines.

21. When Would the Hypothesis Be Falsified or Narrowed?

If ordinary input controls, redundancy, circuit breakers, rate limits, and resilience mechanisms consistently prevent cross-actant amplification under realistic conditions, a separate Grid layer may provide little benefit for that scenario. If apparent spread is fully explained by familiar queueing and systems dynamics, the SCW label may add vocabulary but not engineering content. Conversely, if adaptive actants exhibit measurable persistence, unanticipated coupling, or multi-enterprise consequences that existing controls cannot effectively constrain, the proposed Grid response becomes more compelling. GUDIYA must welcome either finding.

22. Legal Authority, Civil Liberties and Institutional Legitimacy

A national supervisor able to limit otherwise authorized AI interactions would wield considerable power. Its legitimacy depends on a narrowly specified mandate, due process, independent oversight, auditable proportionality, privacy-preserving observability, and appeal procedures. It must not classify lawful market behavior, disagreement, or benign innovation as an adversarial weapon merely because those activities perturb the field. Safety enforcement and malicious attribution must remain separable decisions.

23. The Principle in the BLACK OCTOBER Canon

The Standoff Cognitive Weapon Principle

> *An adversary may produce harmful collective consequences by perturbing conditions to which adaptive actants legitimately respond, without first compromising the code, identity, or execution boundary of any participant. Security of the actant and stability of the Cognitive Field are therefore distinct but complementary assurance obligations. The initiating disturbance may be local and temporary; the behavioral consequences may be widespread, transformed, and persistent. GUDIYA proposes continuous field observation and proportionate rendezvous-based stabilization as a defense against such propagation.*

24. Conclusion: The Target Is the Relationship, Not Necessarily the Machine

The depth-charge analogy began with a submerged vessel whose protection strategy centered on preventing a direct hit. A disturbance delivered through the surrounding medium forced naval engineers to consider survivability as a different object of design. In the future AI economy, component security and sandbox integrity remain indispensable, but they cannot by themselves certify that interconnected autonomous behavior will remain dependable when the surrounding operating environment changes.

The Standoff Cognitive Weapon is best treated as a provisional, falsifiable GUDIYA construct. Its importance lies in moving analysis beyond “Was the actant hacked?” toward “What disturbance entered the Cognitive Field, how did healthy actants adapt, and what must be done to protect legitimate undertakings?” If this proposition survives disciplined testing, it strengthens the rationale for Cognitive Field Engineering as a complementary discipline to cybersecurity, software correctness, and organizational resilience.
